

[Name of document] Specification

[Title of the invention] Bactericidal composition containing peptide and chelating agent

[Claims]

[Claim 1] A bactericidal composition comprising as effective ingredients (a) at least one substance selected from the group consisting of ethylenediaminetetraacetic acid and metal salts thereof and (b) at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin.

[Claim 2] The bactericidal composition according to claim 1, wherein the bactericidal composition is a bactericidal composition for food poisoning bacteria.

[Claim 3] The bactericidal composition according to claim 1, wherein the bactericidal composition is a bactericidal composition for cariogenic bacteria or periodontal bacteria.

[Claim 4] The bactericidal composition according to claim 2, wherein the content of said (a) at least one substance selected from the group consisting of ethylenediaminetetraacetic acid and metal salts thereof is 0.05 mM or more and less than 1.5 mM and the content of said (b) at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin is 1 µg/mL or more and 150 µg/mL or less.

[Claim 5] The bactericidal composition according to claim 3, wherein the content of said (a) at least one substance selected

from the group consisting of ethylenediaminetetraacetic acid and metal salts thereof is 0.3 mM or more and less than 15 mM and the content of said (b) at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin is 1 µg/mL or more and 150 µg/mL or less.

[Detailed description of the invention]

[Field of the invention]

The present invention relates to a bactericidal composition containing a peptide and a chelating agent, and more particularly, to a bactericidal composition containing a chelating agent such as ethylenediaminetetraacetic acid and an antibacterial peptide derived from barley as effective ingredients.

[Prior art]

In Japan, the bacteria that cause food poisoning most frequently include Salmonella sp. and Vibrio parahaemolyticus. In recent years, food poisoning due to pathogenic Escherichia coli O-157 is increasing trend. Food poisoning of rice products due to Bacillus cereus occurs every year though in few cases.

To sterilize these food poisoning bacteria contaminating various foods is effective for preventing the food poisoning. Bacteria also cause dental caries and periodontal disease, so that sterilization of such bacteria is also an important problem.

However, consumers tend to dislike chemically synthesized food preservatives and bactericides. Therefore, various efforts have

been made to contrive an efficient mechanism that they can act at low concentrations and to control the bacteria by use of a natural substance derived from a plant.

The antibacterial substance derived from a plant includes allyl isothiocyanate, which is a component of mustard and horseradish, a pectin decomposition product and so forth. These may have a peculiar odor or may require that they must be added in a high concentration to show sufficient bactericidal effect (Control of Food Microbes, Saiwai Shobo, 204-254 (1998)).

A sweetener that cariogenic bacteria cannot assimilate includes a sugar alcohol such as xylitol. It is known that the sugar alcohol will cause diarrhea when it is taken in a large amount (Food and Development, Vol. 29 No. 4, pages 4-7 (1994)).

Furthermore, substances that are effective for the inhibition of growth of periodontal bacteria and for inhibition of collagenase include plant-derived substances such as lignin (Japanese Patent Application Laid-open No. 2000-247900) and polyphenols (Japanese Patent Application Laid-open No. Hei 11-302142). However, these substances must also be used in a relatively high concentration in order to obtain sufficient effects.

Accordingly, a bactericide for food and oral cavity that comprises a safe substance, is odorless and functions at a low concentration is demanded.

It has been known that alpha-type thionin and beta-type thionin,

which are peptides derived from wheat and barley, have effects of inhibiting the growth of fungi and yeast. However, few reports have been made on their effect of inhibiting the growth of bacteria. A report just indicated that 50% inhibitory concentration against growth of E. coli is as low as 250 µg/mL (The Journal of Biological Chemistry, Vol. 267, pages 2228-2233 (1992)).

Furthermore, no report has been thus far made on the antibacterial activity of thionin against other food poisoning bacteria, cariogenic bacteria and periodontal bacteria.

On the other hand, it has been reported that ethylenediaminetetraacetic acid (EDTA) has a chelating action on various metal ions and that it shows antibacterial activity against E. coli and V. parahaemolyticus in a high concentration (10 mM) (Japanese Journal of Bacteriology, Vol. 47, pages 625-629 (1992)). 10 mM disodium salt of EDTA is calculated as 3362 ppm. However, no antibacterial effect against cariogenic bacteria or periodontal bacteria has been known.

Still further, EDTA and metal salts thereof have a color stabilizing effect on food so that they are used as a food additive in USA, etc. However, their acceptable concentration is 36 to 500 ppm for disodium salt of EDTA (Code of Federal Regulations, Title 21: Food and drugs, US Government Printing Office, 1998). Therefore, even if EDTA and metal salts thereof were used alone as a food preservative in their safe concentration range, no antibacterial

effect could be expected.

[Problem to be solved by the invention]

Therefore, an object of the present invention is to provide a bactericidal composition that has a bactericidal effect against food poisoning bacteria, cariogenic bacteria and periodontal bacteria at a low concentration and is highly safe.

[Means for solving the problem]

The first aspect of the present invention relates to a bactericidal composition comprising as effective ingredients (a) at least one substance selected from the group consisting of ethylenediaminetetraacetic acid (sometimes referred to as EDTA hereinafter) and metal salts thereof and (b) at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin.

The second aspect of the present invention relates to a bactericidal composition according to the first aspect of the present invention, in which the bactericidal composition is a bactericidal composition for food poisoning bacteria.

The third aspect of the present invention relates to a bactericidal composition according to the first aspect of the present invention, in which the bactericidal composition is a bactericidal composition for cariogenic bacteria or periodontal bacteria.

The fourth aspect of the present invention relates to a bactericidal composition according to the second aspect of the

present invention, in which the content of the above (a) at least one substance selected from the group consisting of EDTA and metal salts thereof is 0.05 mM or more and less than 1.5 mM and the content of the above (b) at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin is 1 µg/mL or more and 150 µg/mL or less.

The fifth aspect of the present invention relates to a bactericidal composition according to the third aspect of the present invention, in which the content of the above (a) at least one substance selected from the group consisting of EDTA and metal salts thereof is 0.3 mM or more and less than 15 mM and the content of the above (b) at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin is 1 µg/ml or more and 150 µg/ml or less.

[Embodiment of the invention]

The bactericidal composition of the present invention contains at least one substance selected from the group consisting of EDTA and metal salts thereof and at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin as effective ingredients.

EDTA binds to various metal ions. Any metal salt of EDTA may be used as far as it has an objective antibacterial activity. Suitable metal salts of EDTA include, for example, sodium salt, potassium salt and so forth. In particular, disodium salt,

tetrasodium salt, and so forth of EDTA are preferred.

EDTA and its metal salts may be used alone or two or more of them may be used in combination.

Thionins, which are usable in the present invention, can be obtained from flour of grains such as barley, wheat, oats and rye through extraction with aqueous sodium chloride solution or acids such as hydrochloric acid, citric acid, etc. Alternatively, thionins can be produced by use of a genetic recombinant microorganisms or plants containing thionin genes. Both alpha-type and beta-type thionins are featured by being composed of about 45 amino acids, which contain about 8 cysteine residues, have the molecular structure characterized in that partial or every cysteine residues thereof form cross-linking by the disulfide bond or bonds.

Thionins can be purified by concentrating the extract of barley or wheat through salting out with ammonium sulfate, etc., followed by high-performance liquid chromatography or the like. However, even crude purified products obtained in the course of such purification process may be used in the present invention as far as they have an antibacterial activity. The alpha-type and beta-type thionins may be used alone or in combination with each other.

One example of the process of extracting and purifying thionins from barley is described in Planta, Vol. 176, pages 221-229 (1988). In the case where thionins are extracted from other varieties of wheat and barley and purified, this process can be applied.

There have already been known the entire amino acid sequences of thionins from barley, wheat and oats (Plant Molecular Biology, Vol. 26, pages 25-37 (1994)) and the amino acid compositions of thionins of rye (Journal of Agricultural and Food Chemistry, Vol.26, pages 794-796 (1978)). Depending on the variety of the barley or wheat, there may also exist peptides that have substitution, addition or deletion of one or several amino acid residues in comparison with the known amino acid composition or sequence. The thionins that can be used in the present invention may also include these peptides as far as they have the objective antibacterial activity.

EDTA and its metal salts have a color stabilization effect for food and hence they are granted as a food additive in many countries.

In addition, the safety evaluation of EDTA and the like has already been established. ADI (Acceptable Daily Intake) of EDTA or the like as food additive is 2.5 mg/kg body weight (FAO/WHO: Codex Alimentarius Commission, List of additives evaluated for their safety in use in food. CAC/FAL 1-1973 (1973)).

In USA, it is allowed to add EDTA disodium (EDTA-2Na) in a concentration range of 36 to 500 ppm to food (Code of Federal Regulations, Title 21: Food and drugs, US Government Printing Office, 1998).

In consideration of rapid decomposition of thionins by a digestive enzyme such as trypsin (Oita, Journal of the Japanese

Society for Food Science and Technology, Vol. 47, pages 424-430 (2000)), thionin may have a very little, if any, influence on enterobacteria. Furthermore, it has been reported that when guinea pig was administered once with 103 to 229 mg/kg body weight of thionin and observed for 7 days after the administration, no abnormality was observed (Cereal Chemistry, Vol. 19, pages 301-307 (1942)).

The bactericidal composition of the present invention can be applied to various noxious microorganisms, for example, food poisoning bacteria, cariogenic bacteria, periodontal bacteria and so forth.

The bactericidal composition of the present invention may be formulated into various forms. For example, EDTA or its metal salt and thionin may be simultaneously added to various foods. EDTA and its metal salts as well as thionins have heat resistance, so that they may be added to food prior to pasteurize the food.

To sterilize food poisoning bacteria contained in food, it may be advantageous to simultaneously add 0.1 to 0.5 mM EDTA or its metal salt and 2 to 100 µg/mL thionin for V. parahaemolyticus, 0.1 to 1.49 mM EDTA or its metal salt and 2 to 100 µg/mL thionin for Salmonella sp., or 0.5 to 1.49 mM EDTA or its metal salt and 10 to 100 µg/mL thionin for E. coli. However, the lower the concentration of EDTA or its metal salt is, the higher the concentration of thionin to be added must be.

It should be noted that 0.1 to 1.49 mM EDTA-2Na corresponds

to 33.6 to 500 mg/L EDTA-2Na and is identical to or less than 500 ppm, which is the upper limit of the safety standard in U.S.A. However, there is a fear that side effects could occur when 1.50 mM or more EDTA-2Na is added to food.

As described above, the bactericidal composition of the present invention can be used by adding it to foods and also to various oral preparations such as dental powder and mouthwash. In this case, addition of 0.5 to 10 mM EDTA or its metal salt and 4 to 100 µg/ml thionin may be sufficient. Daily use of this composition can remedy or prevent dental caries or periodontal disease.

Hereinafter, the present invention will be illustrated in detail by examples. However, the present invention is not limited thereby.

Production Example 1

300 mL of distilled water was added to 100 g of powdered grains of hull-less barley "Ichibanboshi", a kind of barley, powdered by use of a cyclone mill. After stirring it at 4°C for 1 hour, the mixture was centrifuged and the supernatant was removed.

To the precipitate was added 200 mL of 1 M aqueous sodium chloride solution and the mixture was stirred at 4°C for 2 hours and then centrifuged. The obtained supernatant was subjected to ammonium sulfate (50 to 90% saturation), and the recovered precipitates were suspended in phosphate buffer and centrifuged. The obtained supernatant was subjected to high performance liquid chromatography

to obtain purified alpha-type and beta-type thionins of barley. Using Wakosil 5C4-200, 4.6 mm ϕ \times 250 mm (manufactured by Wako Pure Chemical Industries, Ltd., Osaka, Japan) as the column, concentration gradient elution with water (pH 2.1) containing 0.1% trifluoroacetic acid and 0 to 40% (0 to 40 minutes) acetonitrile was performed at a flow rate of 0.5 mL/minute. The collected fractions were concentrated to dryness by use of a centrifugal evaporator and confirmed to be alpha-type and beta-type thionins by amino acid analysis and mass spectrum analysis. There were obtained 37 mg of alpha-type thionin and 12 mg of beta-type thionin per 1 kg of powdered "Ichibanboshi" grain.

Production Example 2

300 mL of 0.15 N hydrochloric acid was added to 100 g of commercially available soft wheat flour and the mixture was stirred. After standing at 37°C for 30 minutes, the mixture was again stirred and then centrifuged. To the supernatant was dropped 10 N aqueous sodium hydroxide solution to neutralize it, and centrifuged again.

The supernatant thus obtained was subjected to ammonium sulfate (50 to 90% saturation) and the recovered precipitate was suspended in phosphate buffer. The centrifuged supernatant was subjected to high performance liquid chromatography under the same conditions as in Production Example 1 to obtain purified alpha-type thionin of wheat.

The collected fractions were concentrated to dryness by use

of a centrifugal evaporator and confirmed to be alpha-type thionin by amino acid analysis and mass spectrum analysis. Thus 40 mg of alpha-type thionin per 1 kg of soft wheat flour was obtained.

Example 1

Periodontal bacteria (Prevotella nigrescens and Fusobacterium nucleatum) were each inoculated into a GAM broth medium (manufactured by Nissui Pharmaceutical Co., Ltd., Tokyo, Japan) containing 5 µg/ml of hemin and 1 µg/ml of menadione and sealed in Anaeromate (manufactured by Nissui Pharmaceutical Co., Ltd., Tokyo, Japan), followed by anaerobically cultivation at 37°C for 2 days.

Streptococcus mutans, which is a cariogenic bacterium, was inoculated into a brain heart infusion medium (manufactured by Difco, Inc.), Bacillus cereus was inoculated into a sensitive measurement medium (manufactured by Nissui Pharmaceutical Co., Ltd., Tokyo, Japan), and other bacteria such as food poisoning bacteria were inoculated into an LB medium (1% polypeptone, 0.5% yeast extract, 0.5% sodium chloride, pH 7.2) and incubated at 37°C for 1 day.

Then, after adding predetermined amounts of thionin and EDTA, the bacteria were inoculated so that the concentration of bacteria was about 1×10^6 cells/mL. After cultivating cariogenic bacteria for two days whereas other bacteria for 1 day, the viable count was measured by a method of diluted plate culture. The concentration in which the viable count was decreased to 1/100 or less was defined as minimum bactericidal concentration (MBC) and the concentration

in which the viable count was not increased was defined as minimum inhibitory concentration (MIC). The results obtained are shown in Tables 1, 2 and 3, as well as in Fig. 1.

As will be clear from Table 1, when alpha-type thionin of wheat was added alone, the test bacteria except for Salmonella typhimurium JCM 6977 and V. parahaemolyticus IFO 12711 showed an MIC of 50 µg/mL or more. On the other hand, when EDTA-2Na was added alone, Salmonella sp., E. coli and Streptococcus mutans had an MBC of 10 mM or more whereas other bacteria had an MBC of 1 mM or less.

Next, 10 µg/mL of alpha-type thionin of wheat and 0.02 to 10 mM of EDTA-2Na were added simultaneously. In the case of food poisoning bacteria, the MBC of EDTA-2Na was decreased as compared with the addition of EDTA-2Na alone. However, in the case of periodontal bacteria no such synergistic effect was observed.

Also, in the case of EDTA and EDTA-tetrasodium salt (EDTA-4Na), synergistic effects on S. typhimurium JCM 6977 and E. coli JCM 5491 identical to or higher than that of EDTA-2Na were observed (cf. Table 2).

Furthermore, the MBC of alpha-type thionin of wheat on S. typhimurium JCM 6977, E. coli JCM 5491 and V. parahaemolyticus IFO 12711 in the presence of EDTA-2Na in different concentrations was examined, and the results as shown in Fig. 1 were obtained. The tests were carried out by cultivation in an LB medium at 37°C for 1 day. In Fig. 1, the symbol ● indicates S. typhimurium JCM 6977,

○ indicates E. coli JCM 5491 and □ indicates V. parahaemolyticus IFO 12711. Concerning the antibacterial activity of thionin in the coexistence of EDTA-2Na, substantially no difference was observed between the thionin derived from wheat and the thionin derived from barley, and also between the alpha-type and the beta-type (Table 3).

* LB medium containing EDTA-2Na (1 mM) was used.

Example 2

The MIC of alpha-type thionin of wheat on Streptococcus mutans JCM 5705 was 50 µg/ml in the brain heart infusion medium (manufactured by Difco, Inc.) (cf. Table 1) but it was 4 µg/ml in peptone water (1% polypeptone, 1% NaCl, pH 7.0) containing 0.5% sucrose, and substantially no acid production from sucrose was observed for 2 days. More particularly, a change in pH of the medium was examined when S. mutans was inoculated into the medium such that the microbial concentration in the medium was 2×10^6 cells/ml and cultured at 37°C (cf. Fig. 2). Fig. 2 is a graph illustrating the influence of alpha-type thionin of wheat on acid production by S. mutans. In Fig. 2, the symbol ○ indicates no addition of wheat alpha-type thionin, □ indicates addition of 3 µg/ml of the thionin, △ indicates addition of 4 µg/ml of the thionin, and ▽ indicates addition of 5 µg/ml of the thionin.

It has been reported that human saliva contains usually 1 to 4 mM of calcium (Archives of Oral Biology, 44, 111-117 (1999)), and that the antibacterial activity of thionin to yeast was decreased by calcium (Agricultural and Biological Chemistry, 37, 2289-2249

(1973)).

Accordingly, it was examined how calcium influenced the inhibition of thionin on the acid production by S. mutans. As a result, it was observed that calcium suppressed the inhibition similar to yeast. It was also observed that addition of the same molar concentration of EDTA-2Na as calcium dissolved the suppression by calcium against inhibition of the acid production (cf. Fig. 3). More particularly, S. mutans was inoculated in the above-mentioned peptone water containing 0.5% sucrose such that the microbial concentration was 2×10^6 cells/ml and cultured at 37°C for 24 hours. Then the pH of the medium was measured. In Fig. 3, the symbol ○ indicates addition of CaCl_2 alone and ● indicates simultaneous addition of CaCl_2 and EDTA-2Na.

[Effect of the invention]

According to the present invention, there is provided a bactericidal composition comprising as active ingredients (a) at least one substance selected from the group consisting of EDTA and metal salts thereof and (b) at least one substance selected from the group consisting of alpha-type thionin and beta-type thionin.

The ingredients (a) and (b) exhibit sterilizing effects at low concentrations so that food poisoning bacteria can be effectively sterilized by addition of the bactericidal composition of the present invention to various foods. By addition of the bactericidal composition to various oral preparations in order to sterilize

cariogenic bacteria and periodontal bacteria, prevention and treatment of dental caries and periodontal diseases can be expected.

Aqueous solutions of EDTA or its metal salts and of thionin are each colorless, transparent and odorless, so that they give no influence on the taste of food and so forth.

[Brief description of the drawings]
